

What is Claimed is:

1. A hearing aid for amplifying an acoustic signals, comprising:

a controller for detecting in real time a frequency band at the highest level of the acoustic signals through frequency analysis of the acoustic signals that vary over time, and for generating a control signal to raise a gain for signals of a higher frequency range than the detected frequency band at the highest level; and

a first amplifier, in which the control signal from said controller is inputted, for amplifying the acoustic signals by increasing the gain for signals of the higher frequency range than the frequency band, wherein frequency characteristics of the first amplifier are controlled depending on the detected frequency band.

2. A hearing aid for amplifying an acoustic signals, comprising:

an A/D converter provided on the side where the acoustic signals are inputted, for converting analog signals of the acoustic signals into digital signals;

a digital signal processor for detecting in real time a frequency band at the highest level of the digital signals through frequency analysis of the digital signals that are outputted from the A/D converter and vary over time, and then for generating a control signal for raising a gain for signals of a higher frequency range than the detected frequency band at the highest level, and then for amplifying the digital signals by increasing the gain for signals of the higher frequency range than the detected frequency band, according to the control signal; and

a D/A converter for converting the digital signals outputted from the digital signal processor into analog signals.

3. A hearing aid for amplifying an input acoustic signals that vary over time, comprising:

a control circuit for detecting a first frequency band at the highest level of the input acoustic signals and for generating a control signal according to the detected first frequency band; and

an amplifier for amplifying the input acoustic signals so as to generate an output acoustic signals, wherein the amplifier has a frequency characteristic including a first gain region which has a constant gain for frequencies equal to or lower than the detected first frequency band, and a second gain region whose gain increases higher than the first gain region, according to frequency, for frequencies higher than the detected first frequency band;

and in response to the control signal, an increase point between the first and second gain regions changes according to the detected first frequency band.

4. A hearing aid, comprising:

a detecting circuit for detecting in real time a first frequency band at the highest level of input acoustic signals that vary over time; and

an amplifier for amplifying an input acoustic signals that vary over time and generating an output acoustic signals, and

wherein the amplifier has a frequency characteristic including a first gain region which has a constant gain for frequencies equal to or lower than the first frequency band, and a second gain region whose gain increases higher than the first gain region, according to frequency, for frequencies higher than the detected first frequency band; and an increase point between the first and second gain regions changes according to the detected first frequency band.

5. A hearing aid, comprising:

an analog-to-digital processor converting an analog audio signal into a digital audio signal;

a digital signal processor detecting a first formant frequency in the digital audio signal and amplifying components of the digital audio signal having a frequency higher than the first formant responsive to the detection; and

a digital-to-analog converter coupled to the digital signal processor and converting the digital audio signal into an analog audio signal.

6 A hearing aid processing method, comprising:

detecting a first formant frequency in the digital audio signal; and

amplifying components of the digital audio signal having a frequency higher than the first formant responsive to the detecting.
